

Software security, secure programming

Reverse-engineering from binary code

Master M2 Cybersecurity

Academic Year 2023 - 2024

Outline

Introduction

Low-level code representations

Disassembling

Retrieving source-level information

Bonus: Dynamic source-level information recovery

Some Tools ...

Software = several knowledge/information levels

- ▶ (formal) models: overall architecture, component behaviors
- ▶ specifications, algorithms, abstract data structures
- ▶ source code
 - objects, variables, types, functions, control and data flows
- ▶ possible intermediate representations: Java bytecode, LLVM IR, etc.
- ▶ assembly
- ▶ binary code (relocatable / shared object / executable)

Some reverse-engineering settings:

- ▶ source level → model level ...
- ▶ de-compiling: binary → source level
- ▶ disassembling: binary → assembly level
- ▶ etc.

Why and when bothering with binary code ? (1)

Why and when bothering with binary code ? (1)

→ when the source code is not/no longer **available**

- ▶ updating/maintaining legacy code
- ▶ “off-the-shell” components (COST), external libraries
- ▶ dynamically loaded code (applets, plugins, mobile apps)
- ▶ pieces of assembly code in the source
- ▶ suspicious files (malware, etc.)

Why and when bothering with binary code ? (2)

→ when the source code is not **sufficient**

“What You See Is Not What You Execute” [T. Reps]

- ▶ untrusted compilation chain
- ▶ low-level bugs, at the HW/SW interface
- ▶ **security analysis**
going beyond standard programming language semantics
(optimization, memory layout, undefined behavior, protections, etc.)

Why and when bothering with binary code ? (2)

→ when the source code is not **sufficient**

“What You See Is Not What You Execute” [T. Reps]

- ▶ untrusted compilation chain
- ▶ low-level bugs, at the HW/SW interface
- ▶ **security analysis**
going beyond standard programming language semantics
(optimization, memory layout, undefined behavior, protections, etc.)

Beware ! Reverse-engineering is restricted by the law
("Intellectual Property", e.g. Art. L122-6-1 du Code de la Propriété Intellectuelle)

Outline

Introduction

Low-level code representations

Disassembling

Retrieving source-level information

Bonus: Dynamic source-level information recovery

Some Tools ...

Example 1: Java ByteCode (stack machine)¹

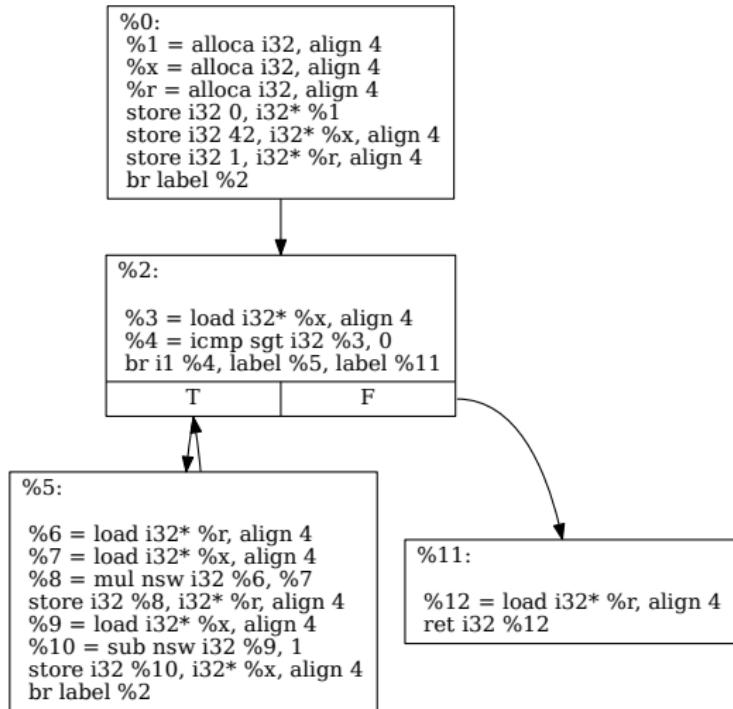

```
public static int main(java.lang.String[]);
Code:
    0: bipush          42
    2: istore_1
    3: iconst_1
    4: istore_2
    5: iload_1
    6: ifle            20
    9: iload_2
   10: iload_1
   11: imul
   12: istore_2
   13: iload_1
   14: iconst_1
   15: isub
   16: istore_1
   17: goto           5
   20: iload_2
   21: ireturn
```

public static int main() {
 int x, r;
 x=42 ; r=1 ;
 while (x>0) {
 r = r*x;
 x = x-1;
 } ;
 return r ;
}

¹use javap -c to produce the bytecode

Example 2: LLVM IR (register based machine)

```
int main() {
    int x, r;
    x=42 ; r=1 ;
    while (x>0) {
        r = r*x;
        x = x-1;
    }
    return r ;
}
```

Example 3: assembly code (x86)²

```
main:  
        pushl %ebp  
        movl %esp,%ebp  
        subl $8,%esp  
        movl $42,-4(%ebp)  
        movl $1,-8(%ebp)  
  
int main() {  
    int x, r;  
    x=42 ; r=1 ;  
    while (x>0) {  
        r = r*x;  
        x = x-1;  
    } ;  
    return r ;  
}  
.L2:  
        cmpl $0,-4(%ebp)  
        jle .L3  
        movl -8(%ebp),%edx  
        imull -4(%ebp),%edx  
        movl %edx,-8(%ebp)  
        decl -4(%ebp)  
        jmp .L2  
.L3:  
        movl -8(%ebp),%eax  
        jmp .L1  
.L1:  
        leave  
        ret
```

²see <https://godbolt.org/>

Example 4: assembly code (x86-64)³

```
main:  
    push    rbp  
    mov     rbp, rsp  
    mov     DWORD PTR [rbp-4], 42  
    mov     DWORD PTR [rbp-8], 1  
    jmp     .L2  
  
int x, r;  
x=42 ; r=1 ;  
    r = r*x;  
    x = x-1;  
} ;  
return r ;  
.  
.L3:  
    mov     eax, DWORD PTR [rbp-8]  
    imul   eax, DWORD PTR [rbp-4]  
    mov     DWORD PTR [rbp-8], eax  
    sub    DWORD PTR [rbp-4], 1  
  
.L2:  
    cmp    DWORD PTR [rbp-4], 0  
    jg     .L3  
    mov     eax, DWORD PTR [rbp-8]  
    pop    rbp  
    ret
```

³see <https://godbolt.org/>

Memory layout at runtime (simplified)

Executable code = (binary) file produced by the compiler
→ need to be **loaded** in memory to be executed (using a loader)

However:

- ▶ no absolute addresses are stored in the executable code
→ decided at “load time”
 - ▶ not all the executable code is stored in the executable file
(e.g., dynamic libraries)
 - ▶ data memory can be dynamically allocated
 - ▶ data can become code (and conversely ...)
 - ▶ etc.
- the executable file should contain all the information required ...

Memory layout at runtime (simplified)

Executable code = (binary) file produced by the compiler
→ need to be **loaded** in memory to be executed (using a loader)

However:

- ▶ no absolute addresses are stored in the executable code
→ decided at “load time”
 - ▶ not all the executable code is stored in the executable file
(e.g., dynamic libraries)
 - ▶ data memory can be dynamically allocated
 - ▶ data can become code (and conversely ...)
 - ▶ etc.
- the executable file should contain all the information required ...
- ☰ standards executable formats: ELF (Linux), PE (Windows), etc.
- ▶ header
 - ▶ sections: text, initialized/uninitialized data, symbol tables, relocation tables, etc.
- Rks:** **stripped** (no symbol table) vs **verbose** (debug info) executables ...

Example 1: Linux Elf

x86 (32) assembly language in one slide

Registers:

- ▶ stack pointer (ESP), frame pointer (EBP), program counter (EIP)
- ▶ general purpose: EAX, EBX, ECX, EDX, ESI, EDI
- ▶ flags

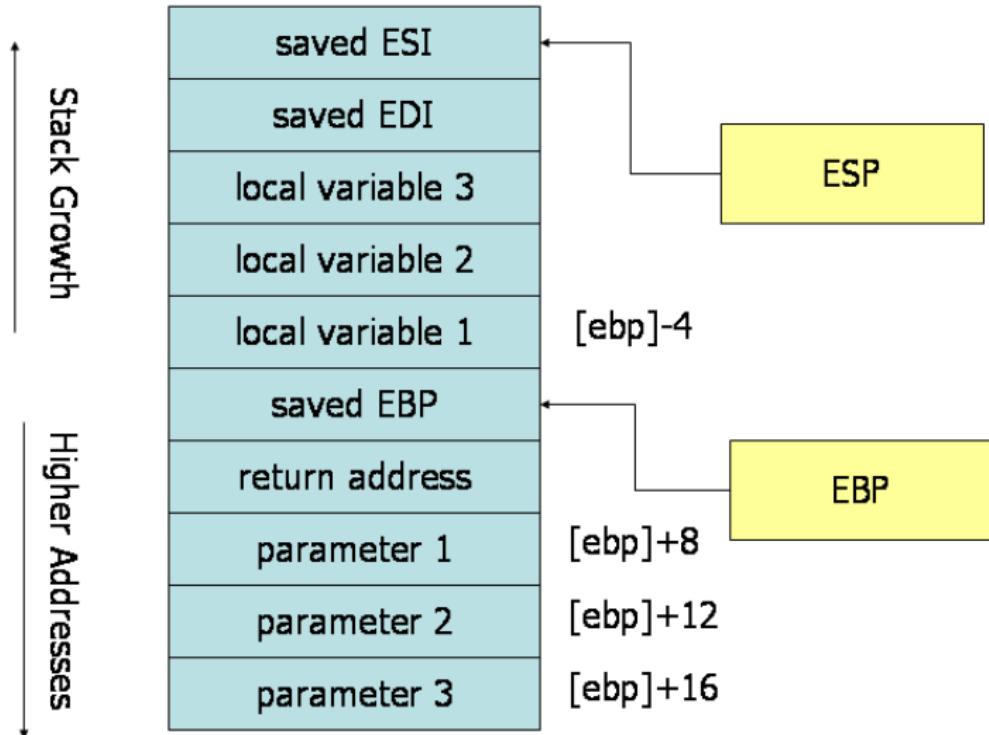

Instructions:

- ▶ data transfer (MOV), arithmetic (ADD, etc.)
- ▶ logic (AND, TEST, etc.)
- ▶ control transfer (JUMP, CALL, RET, etc)

Addressing modes:

- ▶ register: mov eax, ebx
- ▶ immediate: mov eax, 1
- ▶ direct memory: mov eax, [esp+12]

Stack layout for the x86 32-bits architecture

x86_64 assembly language in one slide

Registers:

- ▶ stack pointer (RSP), frame pointer (RBP), program counter (RIP)
- ▶ general purpose: RAX, RBX, RCX, RDX, RSI, RDI
- ▶ flags

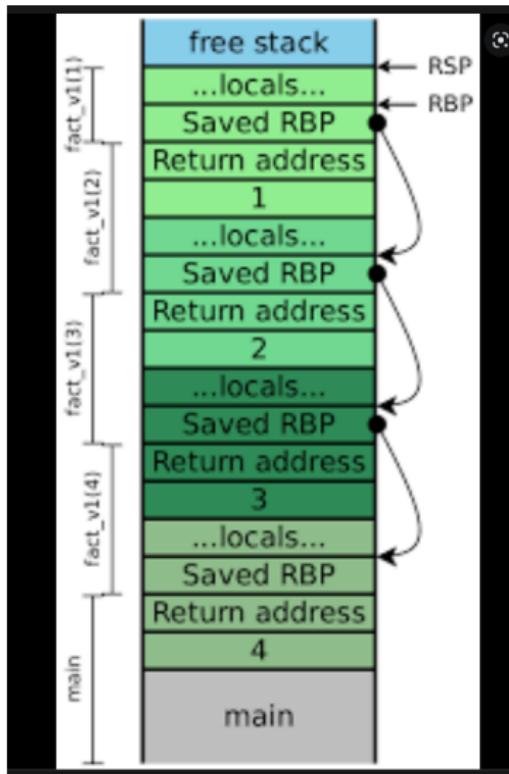

Instructions:

- ▶ data transfer (MOV), arithmetic (ADD, etc.)
- ▶ logic (AND, TEST, etc.)
- ▶ control transfer (JUMP, CALL, RET, etc)

Addressing modes (AT&T syntax):

- ▶ register: movl %rax, %rbx // $\text{rbx} \leftarrow \text{rax}$
- ▶ immediate: movl \$1, %rax // $\text{rax} \leftarrow 1$
- ▶ direct memory: movl %rax, -0x10(%rbp) // $\text{Mem}[\text{rbp}-16] \leftarrow \text{rax}$

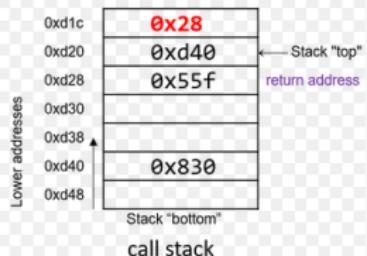

Stack layout for the x86 64-bits architecture (1)

Stack layout for the x86 64-bits architecture (2)

```
x 0x526 <assign>:  
0x526 push %rbp  
0x527 mov %rsp, %rbp  
→ 0x52a mov $0x28, -0x4(%rbp)  
0x531 mov -0x4(%rbp), %eax  
0x534 pop %rbp  
0x535 retq  
0x542 <main>:  
0x542 push %rbp  
0x543 mov %rsp, %rbp  
0x546 sub $0x10, %rsp  
0x54a callq 0x526 <assign>  
0x55f callq 0x536 <adder>  
0x554 mov %eax, -0x4(%rbp)  
0x557 mov -0x4(%rbp), %eax  
0x55a mov %eax, %esi
```

Registers	
%eax	0x0
%edi	1
%rsp	0xd20
%rbp	0xd20
%rip	0x531

Terminal:

```
$ ./prog
```

ABI (Application Binary Interface)

to “standardize” how processor resources should be used
⇒ required to ensure compatibilities at binary level

- ▶ sizes, layouts, and alignments of basic data types
- ▶ **calling conventions**
 - argument & return value passing, saved registers, etc.
- ▶ system calls to the operating system
- ▶ the binary format of object files, program libraries, etc.

	Cleans Stack	Arguments	Arg Ordering
cdecl	Caller	On the Stack	Right-to-left
fastcall	Callee	ECX,EDX, then stack	Left-to-Right
stdcall	Callee	On the Stack	Left-to-Right
VC++ thiscall	Callee	EDX (this), then stack	Right-to-left
GCC thiscall	Caller	On the Stack (this pointer first)	Right-to-left

Figure: some calling conventions

Disassembling !

statically:

disassemble the **whole** file content **without executing it ...**

dynamically: disassemble the **current** instruction path **during execution/emulation ...**

Static Disassembling (1)

Assume “reasonable” (stripped) code only

→ no obfuscation, no packing, no auto-modification, ...

Enough pitfalls to make it undecidable ...

main issue: distinguishing code vs data ...

- ▶ interleavings between code and data segments
- ▶ dynamic jumps (`jmp <register>`)
- ▶ possible variable-length instruction encoding, # addressing modes, ...
 - e.g., > 1000 distinct x86 instructions

1.5 year to fix the semantics of x86 shift instruction at CMU

Static Disassembling (1)

Assume “reasonable” (stripped) code only

→ no obfuscation, no packing, no auto-modification, ...

Enough pitfalls to make it undecidable ...

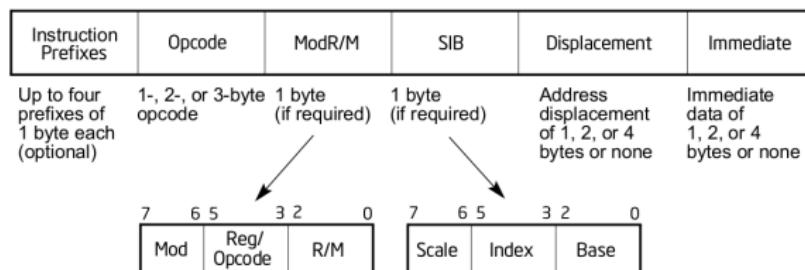

main issue: distinguishing **code vs data** ...

- ▶ interleavings between code and data segments
- ▶ dynamic jumps (`jmp <register>`)
- ▶ possible variable-length instruction encoding, # addressing modes, ...
e.g., > 1000 distinct x86 instructions

1.5 year to fix the semantics of x86 shift instruction at CMU

→ much worse when considering **self-modifying code, packers**, etc.

Example: x86 instruction format

Static Disassembling (2)

Classical static disassembling techniques

- ▶ linear sweep: follows increasing addresses (ex: `objdump`)
 → pb with interleaved code/data ?
- ▶ recursive disassembly: control-flow driven (ex: `IDAPro`)
 → pb with dynamic jumps ?
- ▶ hybrid: combines both to better detect errors ...

Some existing tools

- ▶ Ghidra
 Developed by the NSA, ∃ a free version, # useful features
- ▶ IDA Pro
 a well-known commercial disassembler, # useful features
- ▶ On Linux platforms (for ELF formats):
 - ▶ `objdump` (-S for code disassembling)
 - ▶ `readelf`
- ▶ and many others (Capstone, Radare2, Miasm, etc.)

Rk: may produce assembly-level IR instead of native assembly code
→ simpler language (a few instruction opcodes), explicit semantics (no side-effects), share analysis back-ends

Static disassembly (cont'd)

See some Emmanuel Fleury slides . . .

Indirect Jumps

BRANCH R_i

(branch address computed at runtime and stored inside register R_i)

⇒ A critical issue for **static** disassemblers/analysers ...

Occurs when compiling:

- ▶ some switch statements
- ▶ high-order functions (with function as parameters and/or return values)
- ▶ pointers to functions
- ▶ dynamic method binding in OO-languages, virtual calls
- ▶ etc.

Example of Indirect Jump

(borrowed from E. Fleury)

Source code example:

```
enum {DIGIT, AT, BANG, MINUS}
f (char c) {
switch(c) {
case '0': case '1': case '2': case '3': case '4':
case '5': case '6': case '7': case '8': case '9': return DIGIT ;
case '@': return AT ;
case '!': return BANG ;
case '-': return MINUS ;
}
}
```

⁴See <https://godbolt.org/>

Example of Indirect Jump

(borrowed from E. Fleury)

Source code example:

```
enum {DIGIT, AT, BANG, MINUS}
f (char c) {
switch(c) {
case '0': case '1': case '2': case '3': case '4':
case '5': case '6': case '7': case '8': case '9': return DIGIT ;
case '@': return AT ;
case '!': return BANG ;
case '-': return MINUS ;
}
```

Code produced with x86-64 gcc8.2⁴

```
f:
    push    rbp
    mov     rbp,  rsp
    mov     eax,  edi
    mov     BYTE PTR [rbp-4], al
    movsx   eax,  BYTE PTR [rbp-4]
    sub     eax,  33          ; Ascii for '!'
    cmp     eax,  31          ; 64 is Ascii for '@'
    ja      .L2              ; out of bounds ...
    mov     eax,  eax
    mov     rax,  QWORD PTR .L4[0+rax*8] ; offset in a jump table
    jmp     rax
```

⁴See <https://godbolt.org/>

Dynamic disassembly

Main advantage: disassembling process **guided by** the execution

- ▶ ensures that **instructions only** are disassembled
- ▶ the whole execution context is available (registers, flags, addresses, etc.)
- ▶ dynamic jump destinations are resolved
- ▶ dynamic libraries are handled
- ▶ etc.

However:

- ▶ only a **(small) part** of the executable is disassembled
- ▶ need some suitable **execution platform**, e.g.:
 - ▶ emulation environment
 - ▶ binary level code instrumentation
 - ▶ (scriptable) debugger
 - ▶ etc.

Outline

Introduction

Low-level code representations

Disassembling

Retrieving source-level information

Bonus: Dynamic source-level information recovery

Some Tools ...

Objectives

When the code has been (partially !) disassembled ...

... how to retrieve useful **source-level** information ?
(e.g.: variables, types, functions, control and data-flow relations, etc.)

Challenges

Still a **gap** between assembly and source-level code ...

- ▶ basic source elements lost in translation:
functions, variables, types, (conditionnal) expressions, ...
- ▶ pervasive address computations (addresses = values)
- ▶ etc.

Rk: \neq between code produced by a compiler and written by hand
(structural patterns, calling conventions, ...)

Again, \exists static and dynamic approaches ...

Function identification

Retrieve functions boundaries in a stripped binary code ?

Why is it difficult ?

- ▶ not always clean call/ret patterns:
optimizations, multiple entry points, inlining, etc.
- ▶ not always clean code segment layout:
extra bytes (\notin any function), non-contiguous functions, etc.

Possible solution ...

- ▶ from pattern-matching on (manually generated) binary signatures
 - ▶ simple ones (push [ebp]) or advanced heuristics as in [IDAPro]
 - ▶ standard library function signature database (FLIRT)
- ▶ ...
- ▶ to supervised machine learning classification ...

→ no “sound and complete” solutions ...

Variable and type recovery

2 main issues

- ▶ retrieve the memory layout (stack frames, heap structure, etc.)
- ▶ infer size and (basic) type of each accessed memory location

Variable and type recovery

2 main issues

- ▶ retrieve the memory layout (stack frames, heap structure, etc.)
- ▶ infer size and (basic) type of each accessed memory location

Memory Layout

“addresses” of global/local variables, parameters, allocated chunks

- ▶ static basic access patterns ($\text{epb} + \text{offset}$) [IDAPro]
- ▶ Value-Set-Analysis (VSA)

Variable and type recovery

2 main issues

- ▶ retrieve the memory layout (stack frames, heap structure, etc.)
- ▶ infer size and (basic) type of each accessed memory location

Memory Layout

“addresses” of global/local variables, parameters, allocated chunks

- ▶ static basic access patterns ($\text{epb} + \text{offset}$) [IDAPro]
- ▶ Value-Set-Analysis (VSA)

Types

- ▶ dynamic analysis:
type chunks (library calls) + loop pattern analysis (arrays)
- ▶ static analysis: VSA + Abstract Structure Identification
- ▶ Proof-based decompilation relation inference
type system + program witness [POPL 2016]

Static variable recovery

Retrieve the **address** (and size) of each program “variable” ?

Difficult because:

- ▶ addresses and other values are not distinguishable
- ▶ address \leftrightarrow variable is not one-to-one
- ▶ address arithmetic is pervasive
- ▶ both direct and indirect memory addressing

Static variable recovery

Retrieve the **address** (and size) of each program “variable” ?

Difficult because:

- ▶ addresses and other values are not distinguishable
- ▶ address \leftrightarrow variable is not one-to-one
- ▶ address arithmetic is pervasive
- ▶ both direct and indirect memory addressing

Memory regions + abstract locations

A memory model with 3 distinct regions:

- ▶ Global: global variables
 - ▶ Local: local variables + parameters (1 per proc.)
 - ▶ Dynamic: dynamically allocated chunks
 - ▶ Registers
- ↪ associates a relative address to each variable (**a-loc**)

The so-called “naive” approach (IDAPro)

Heuristic

Addresses used for **direct** variable accesses are:

- ▶ **absolute** (for globals + dynamic)
 - ▶ relative w.r.t **frame/stack pointer** (for globals)
- can be statically retrieved with simple patterns ...

Limitations

- ▶ variables indirectly accessed (e.g., `[eax]`) are not retrieved
(e.g., structure fields)
 - ▶ array = (large) contiguous block of data
- ⇒ Fast recovery technique, can be used as a bootstrap
But coarse-grained information, may hamper further analyses ...

Example

```
typedef struct  
{int i ; char c ;} S ;
```

```
int main() {  
    S x, a[10] ;  
    char *p1 ; int *p2 ;  
    p1 = &(a[9].c) ;  
    p2 = &(x.i) ;  
    return 0 ;  
}
```

a	-60
x.i	-10
p2	-8
p1	-4

```
var_60= byte ptr -60h  
var_10= byte ptr -10h  
var_8= dword ptr -8  
var_4= dword ptr -4  
  
push    ebp  
mov     ebp, esp  
sub     esp, 60h  
lea     eax, [ebp+var_60]  
add     eax, 4Ch  
mov     [ebp+var_4], eax  
lea     eax, [ebp+var_10]  
mov     [ebp+var_8], eax  
mov     eax, 0  
leave  
ret  
main endp
```

Going beyond: Value Set Analysis (VSA)

Compute the contents of each a-loc at each program location ...

... as an **over-approximation** of:

- ▶ the set of (integer) values of each data at each prog. loc.
 - ▶ the addresses of “new” a-locs (indirectly accessed)
- combines simultaneously numeric and pointer-analysis
- Rk:** should be also combined with CFG-recovery ...

⇒ Can be expressed as a forward data-flow analysis ...

Going beyond: Value Set Analysis (VSA)

Compute the contents of each a-loc at each program location ...

... as an **over-approximation** of:

- ▶ the set of (integer) values of each data at each prog. loc.
 - ▶ the addresses of “new” a-locs (indirectly accessed)
- combines simultaneously numeric and pointer-analysis
- Rk:** should be also combined with CFG-recovery ...

⇒ Can be expressed as a forward data-flow analysis ...

A building block for many other static analysis ...

- ▶ function “signature” (size and number of parameters)
- ▶ data-flow dependencies, taint analysis
- ▶ alias analysis
- ▶ type recovery, abstract structure identification
- ▶ etc.

Example: data-flow analysis

Does the value of `y` depend from `x` ?

```
int x, *p, y;  
x = 3 ;  
p = &x ;  
...  
y = *p + 4 ; // data-flow from x to y ?
```

At assembly level:

1. needs to **retrieve** `x` address
2. needs to **follow** memory transfers from `x` address ...

```
mov [ebp-4], 3 /* x=3 ; */  
lea eax, [ebp-4]  
mov [ebp-8], eax /* p = &x ; */  
mov eax, [ebp-8]  
  
... /* follow operations on eax ...  
  
mov eax, [eax] /* y = *p+4 ; ??? */  
add eax, 4  
mov [ebp-12], eax
```

CFG construction

Main issue

handling dynamic jumps (e.g., `jmp eax`) due to:

- ▶ switch statements (“jump table”)
- ▶ function pointers, trampoline, object-oriented source code, ...

Some existing solutions

- ▶ heuristic-based approach (“simple” switch statements) [IDA]
- ▶ abstract interpretation: interleaving between VSA and CFG expansion
 - ▶ use of dedicated abstract domains
 - ▶ use of under-approximations ...

Rk: may create many program “entry points” ⇒ many CFGs ...

Outline

Introduction

Low-level code representations

Disassembling

Retrieving source-level information

Bonus: Dynamic source-level information recovery

Some Tools ...

An (ultra) lightweight dynamic technique

Starting from a binary code ...

- ▶ without source, debug information, symbol table
- ▶ but those architecture and calling convention is known
- ▶ and which can be instrumented & executed

... retrieve function-level information

- ▶ function arity and signatures
 - ▶ quantified coarse grain data-flow information between functions
- within a **single code execution**

General approach

A 3-steps process

1. a lightweight dedicated binary code instrumentation to collect runtime information
2. the one trace execution step to generate a log file
3. an offline log analysis to produce the results ...

Relying on aggressive heuristics to approximate the notion of parameter, type and data-flow ...

Main heuristics

parameter definition

a memory location read before written is a input parameter
(holds also accross function boundaries)

Main heuristics

parameter definition

a memory location read before written is a input parameter
(holds also accross function boundaries)

type definition

- ▶ *ADDR* types can be deduced from load/store operations
- ▶ once an *ADDR*, always an *ADDR*
- ▶ non *ADDR* values are of type *NUM*

Main heuristics

parameter definition

a memory location read before written is a input parameter
(holds also accross function boundaries)

type definition

- ▶ *ADDR* types can be deduced from load/store operations
- ▶ once an *ADDR*, always an *ADDR*
- ▶ non *ADDR* values are of type *NUM*

data-flow definition

- ▶ consider only *ADDR* flows
- ▶ *ADDR* collisions are not fortuitous:
ADDR value *a* produced by *foo* and consumed by *bar* \Rightarrow data-flow from *foo* to *bar* ...

Implementation

SCAT, open source: <https://github.com/Frky/scat>

- ▶ dynamic code instrumentation using PIN
 - function detection based on call/ret instructions
- ▶ minimize the size of the instrumentation code
 - extra implementation level heuristics
 - (e.g., a value between two *ADDR* is an *ADDR*)
- ▶ user given *MIN_CALL* threshold
- ▶ embeds an oracle⁵ for function signatures

Experiments:

- ▶ coreutils (> 100 pgms)
- ▶ 10 common Linux pgms: git, grep, mupdf, objdump, openssl, etc.

⁵based on clang

Experimental results: arity

overview

prototypes

address flow

arity

Outline

Introduction

Low-level code representations

Disassembling

Retrieving source-level information

Bonus: Dynamic source-level information recovery

Some Tools ...

IDA Pro [HexRays]

A swiss-knife for reverse engineering ...

- ▶ Commercial disassembler and debugger
- ▶ Supports 50+ processors (intel, ARM, .NET, PowerPC, MIPS, etc.)
- ▶ Recognizes **library functions** FLIRT (C/C++ only)
- ▶ Builds call graphs and CFGs
- ▶ Tags **arguments/local variables**
- ▶ Rename labels (variables names etc.)
- ▶ Provides **scripting environment** (IDC, Python) and debugging facilities

Script example

```
#include <idc.idc>
/* this IDA pro script enumerate all funtions and prints info about them */
static main()
{
    auto addr, end, args, locals, frame, firstArg, name, ret;
    addr=0;
    for ( addr=NextFunction(addr); addr != BADADDR; addr=NextFunction(addr) )
    {
        name=Name(addr);
        end= GetFunctionAttr(addr, FUNCATTR_END);
        locals=GetFunctionAttr(addr, FUNCATTR_FRSIZE);
        frame=GetFunctionAttr(addr, FUNCATTR_FRAME);
        ret=GetMemberOffset(frame, " r");
        if (ret == -1) continue;
        firstArg=ret +4;
        args=GetStrucSize(frame) -firstArg;
        Message("function %s start at %x, end at %x\n",name, addr, end);
        Message("Local variables size is %d bytes\n",locals);
        Message("arguments size %d (%d arguments)\n",args, args/4);
    }
}
```

PIN [Intel]

A swiss-knife for binary-level dynamic analysis ...

A dynamic code instrumentation framework

- ▶ run time instrumentation on the binary files
- ▶ provides APIs to define **insertion points** and **callbacks**
(e.g., after specific inst., at each function entry point, etc.)
- ▶ Free for non-commercial use, works on Linux and windows

Example: instruction counting

```
#include "pin.h"
UINT64 icount = 0;
void docount() { icount++; }

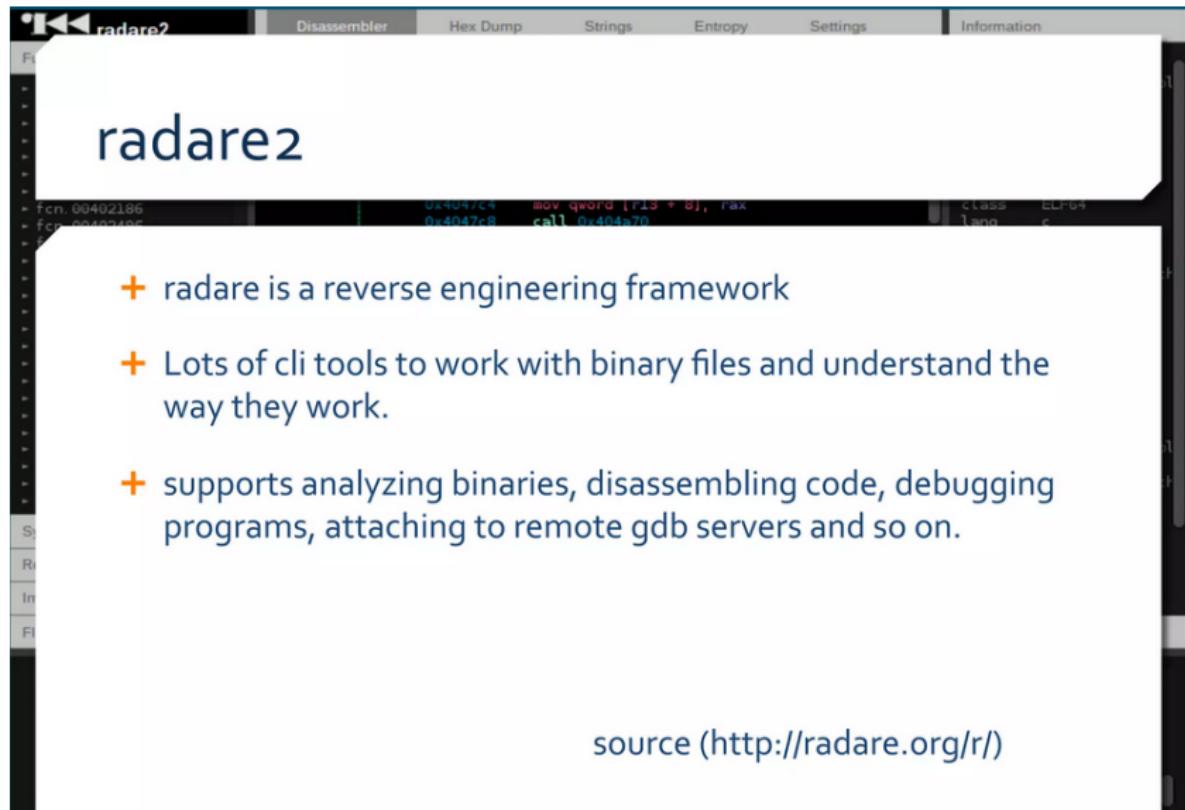

void Instruction(INS ins, void *v)
{
INS_InsertCall(ins, IPOINT_BEFORE, (AFUNPTR)docount, IARG_END);
}

void Fini(INT32 code, void *v)
{ std::cerr << "Count " << icount << endl; }

int main(int argc, char * argv[])
{
PIN_Init(argc, argv);
INS_AddInstrumentFunction(Instruction, 0);
PIN_AddFiniFunction(Fini, 0);
PIN_StartProgram();
return 0;
}
```

Radare2 [radare.org]

(from https://fr.slideshare.net/antojoseph007/radare2-an-introduction-by-anto-joseph)

The screenshot shows the radare2 interface. At the top, there's a navigation bar with tabs: Disassembler, Hex Dump, Strings, Entropy, Settings, and Information. Below the navigation bar, the word "radare2" is displayed in a large, stylized font. The main area shows assembly code:

```
fcn.00402186 0x4047c4    mov qword [f10 + 8], rax
fcn.0040218c 0x4047e8    call 0x404a70
```

Below the assembly code, there are several tabs: Class, Lang, ELF64, and C. On the left side, there are vertical scroll bars and some small icons. At the bottom right, there's a link: source (<http://radare.org/r/>)

- + radare is a reverse engineering framework
- + Lots of cli tools to work with binary files and understand the way they work.
- + supports analyzing binaries, disassembling code, debugging programs, attaching to remote gdb servers and so on.

source (<http://radare.org/r/>)

Use Cases

- + Disassemble (and assemble for) many different architectures
- + Debug with local native and remote debuggers (gdb, rap, webui, r2pipe, winedbg, windbg)
- + Perform forensics on file systems and data carving
- + Be scripted in Python, Javascript, Go and more
- + Support collaborative analysis using the embedded webserver
- + Visualize data structures of several file types
- + Patch programs to uncover new features or fix vulnerabilities
- + Use powerful analysis capabilities to speed up reversing
- + Aid in software exploitation

(source : <http://radare.org/r/>)

Support

- + radare2 supports:
- + Architectures 6502, 8051, arm, arc, avr, bf, tms320 (c54x, c55x, c55+), gameboy
csr, dcpu16, dalvik, i8080, mips, m68k, mips, msil, snes, nios II, sh, sparc, rar,
powerpc, i386, x86-64, H8/300, malbolge, T8200, LH5801
- + File formats bios, dex, elf, elf64, filesystem, java, fatmacho, macho, macho-64,
MZ, PE, PE+, TE, COFF, plang, bios, dyldcache, Gameboy and Nintendo DS
ROMs
- + Operating systems Android, GNU/Linux, [Net|Free|Open]BSD, iOS, OSX, QNX,
w32, w64, Solaris, Haiku, FirefoxOS
- + Bindings Vala/Genie, Python (2, 3), NodeJS, LUA, Go, Perl, Guile, php5, newlisp,
Ruby, Java, OCAML and more
